

## Course Summary

|   |   |   |
|---|---|---|
| <b>Object Modelling</b> <ul style="list-style-type: none"> <li>▪ To identify classes and attributes use your common sense</li> <li>▪ A usual approach is to identify anything with characteristics. Such a thing should be made class and its characteristics should be members variables</li> <li>▪ Normally common nouns become classes</li> <li>▪ Proper nouns should be instances of those classes</li> <li>▪ Normally verbs are member functions</li> </ul>        | <b>Constructor</b> <ul style="list-style-type: none"> <li>▪ If you want some code to execute as soon as an object is created, then we can write this code in a constructor e.g. for the purpose of variable initialization</li> <li>▪ We can make multiple different constructors in a class as long as their parameters are different</li> <li>▪ No matter how many constructors are present, each object will use exactly one of them during creation</li> <li>▪ If we don't define a constructor in our class, then compiler-provided default constructor with zero parameters is used for object creation. This means that objects can only be created without passing arguments</li> </ul> | <b>Copy Constructor</b> <ul style="list-style-type: none"> <li>▪ If we create a copy of an object, then copy constructor is used</li> <li>▪ If we don't define a copy constructor, then a compiler-provided copy constructor is used (but it is powerless).</li> <li>▪ There can be only one copy constructor in each class</li> <li>▪ We don't need a copy constructor unless there is DMA in our class</li> <li>▪ If there is DMA and we don't define a copy constructor, then shallow copy happens i.e. copied object will share memory and value</li> <li>▪ If there is DMA and we define our own copy constructor and perform new memory allocation, then deep copy happens</li> <li>▪ If we don't want objects to be copied then we can create our own copy constructor and make it private (to stop object copying)</li> </ul> |
| <b>Abstraction</b> <ul style="list-style-type: none"> <li>▪ In object-oriented programming, we want information and code hiding</li> <li>▪ Class member variables are usually kept private</li> <li>▪ Class member functions are usually kept public</li> <li>▪ To read value of a private variable we usually make a public function (getter function)</li> <li>▪ To update value of a private variable we usually make a public function (setter function)</li> </ul> | <b>Destructor</b> <ul style="list-style-type: none"> <li>▪ There can only be one no destructor in a class and that is without parameters</li> <li>▪ If you want some code to execute when object is being destroyed (going out of scope), then we can write this code in a destructor e.g. deallocating memory, closing file</li> <li>▪ If we don't define a destructor then, then compiler-provided default destructor is used</li> </ul>  | <b>Static</b> <ul style="list-style-type: none"> <li>▪ A static class member variable is common for all objects i.e. if one object changes its value then it will be changed for all other objects as well</li> <li>▪ We can access a static member variable or function by using an object or class (scope resolution)</li> <li>▪ A static function is one that can only use static members of the class</li> <li>▪ We normally use static variables to save values such as revenue or cost</li> </ul>   |

|   |  |  |
|---|--|--|
| <b>Constants</b> <ul style="list-style-type: none"><li>▪ A constant cannot be changed after it is initialized with a value</li><li>▪ In C++, a constant must be initialized in the same line that it is declared</li><li>▪ If a constant is class is not given an initial value, then we must give it an initial value by using member initialization list in all the constructors</li><li>▪ We can create constants with pointers by either making the pointer itself constant, or by making the data constant, or even by making both pointer and data constants</li><li>▪ A constant function is one that cannot modify any member variable of the class</li><li>▪ A constant parameter is one that cannot be modified inside the function</li><li>▪ A constant object is one that can only be used to call constant function of the class</li></ul> |  |  |
|---|--|--|
